DOMAIN WINTER WINNING CAMP

Student Name: Piyush Bhardwaj **UID :22BCS11108**
Branch: CSE **Section/Group:IOT-639/B**

Day 9 : BackTracking

Very Easy:

1. Generate Numbers with a Given Sum

Generate all numbers of length n whose digits sum up to a target value sum, The digits of the number will be between 0 and 9, and we will generate combinations of digits such that their sum equals the target.

Example 1:
Input: n = 2 and sum = 5
Output: 14 23 32 41 50

Example 2:
Input: n = 3 and sum = 5
Output: 104 113 122 131 140 203 212 221 230 302 311 320 401 410 500

Constraints:
1 <= n <= 9: The number of digits must be between 1 and 9.
1 <= sum <= 100: The sum of the digits must be between 1 and 100.
The first digit cannot be zero if n > 1.

CODE:

```
#include <iostream> #include <vector> using namespace std;  void
generateNumbers(int n, int sum, string current, vector<string> &result) {
if (n == 0 && sum == 0) {        result.push_back(current);
return;
    }      if (n == 0 || sum < 0) return;
int start = current.empty() ? 1 : 0;
```

```
for (int i = start; i <= 9; ++i) {          generateNumbers(n - 1, sum -
i, current + to_string(i), result);      }  }

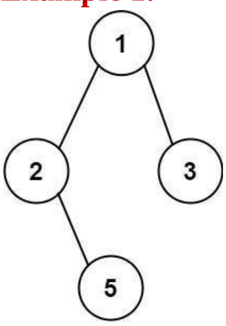
int main() {     int n = 2, sum = 5;
vector<string> result;
generateNumbers(n, sum, "", result);     for
(const string &num : result) {          cout
<< num << " ";
    }
return 0;
}
```

Easy:

2. Binary Tree Paths

Given the root of a binary tree, return all root-to-leaf paths in any order. A leaf is a node with no children.

Example 1:



Input: root = [1,2,3,null,5]Output: ["1->2->5","1->3"] **Example 2:**

Input: root = [1]Output: ["1"]

Constraints:

The number of nodes in the tree is in the range [1, 100]. -100

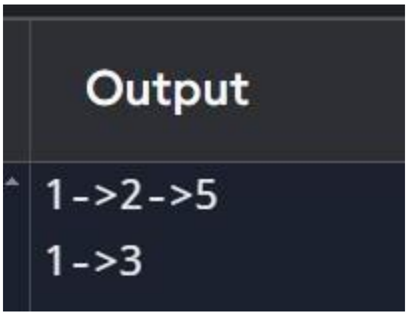
<= Node.val <= 100 CODE:

```
#include <iostream>
#include <vector>
#include <string> using
namespace std;  struct
TreeNode {
   int val;
   TreeNode *left, *right;
   TreeNode(int x) : val(x), left(nullptr), right(nullptr) {}
};

void dfs(TreeNode *root, string path, vector<string> &paths) {
if (!root) return;     path += to_string(root->val);     if (!root-
>left && !root->right) {
paths.push_back(path);
return;
   }
   path += "->";     dfs(root>left,
path, paths);     dfs(root-
>right, path, paths);
}

vector<string> binaryTreePaths(TreeNode *root) {
vector<string> paths;
dfs(root, "", paths);     return
paths;  }  int main() {
   TreeNode *root = new TreeNode(1);     root-
>left = new TreeNode(2);     root->right
= new TreeNode(3);
   root->left->right = new TreeNode(5);

   vector<string> result = binaryTreePaths(root);
for (const string &path : result) {
      cout << path << endl;
   }
return 0;
}
```



Medium:

3. Combinations

Given two integers n and k, return all possible combinations of k numbers chosen from the range [1, n].

You may return the answer in any order.

Example 1:

Input: n = 4, k = 2
Output: [[1,2],[1,3],[1,4],[2,3],[2,4],[3,4]]
Explanation: There are 4 choose 2 = 6 total combinations.
Note that combinations are unordered, i.e., [1,2] and [2,1] are considered to be the same combination. **Example 2:**

Input: n = 1, k = 1
Output: [[1]]
Explanation: There is 1 choose 1 = 1 total combination.

Constraints:

1 <= n <= 20
1 <= k <= n CODE:

```
#include <iostream> #include <vector> using namespace std; void combineHelper(int
start, int n, int k, vector<int> &current, vector<vector<int>>  &result) {      if (k == 0)
{          result.push_back(current);          return;
}
    for (int i = start; i <= n; ++i) {
current.push_back(i);
```

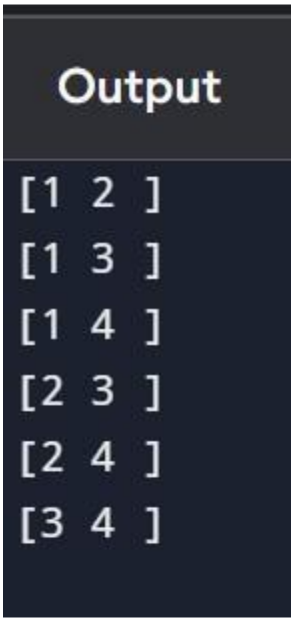
```
        combineHelper(i + 1, n, k - 1, current, result);
current.pop_back();
    }  }

vector<vector<int>> combine(int n, int k) {
vector<vector<int>> result;     vector<int>
current;     combineHelper(1, n, k, current, result);
    return result; }

int main() {

int n = 4, k = 2;

    vector<vector<int>> result = combine(n, k);
for (const auto &comb : result) {
        cout << "[";          for (int num : comb)
cout << num << " ";          cout << "]" <<
endl;
    }
return 0; }
```

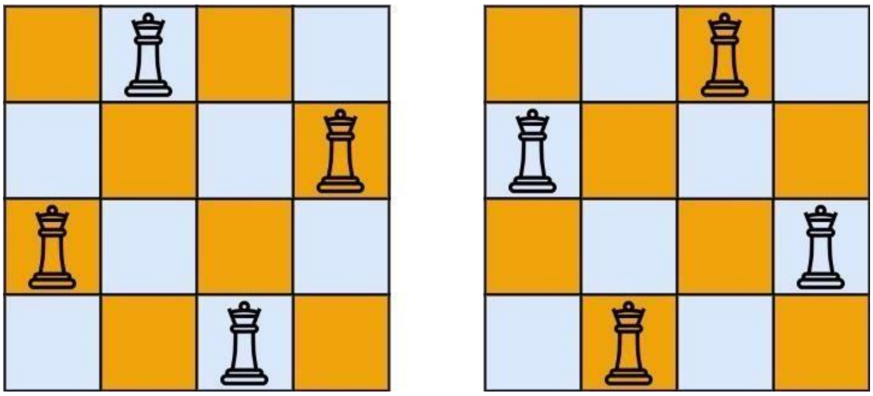


Hard:

4. N-Queens II

The n-queens puzzle is the problem of placing n queens on an n x n chessboard such that no two queens attack each other.
Given an integer n, return the number of distinct solutions to the n-queens puzzle.

Example 1:



Input: n = 4

Output: 2

Explanation: There are two distinct solutions to the 4-queens puzzle as shown.

Example 2:

Input: n = 1

Output: 1

Constraints: 1
<= n <= 9

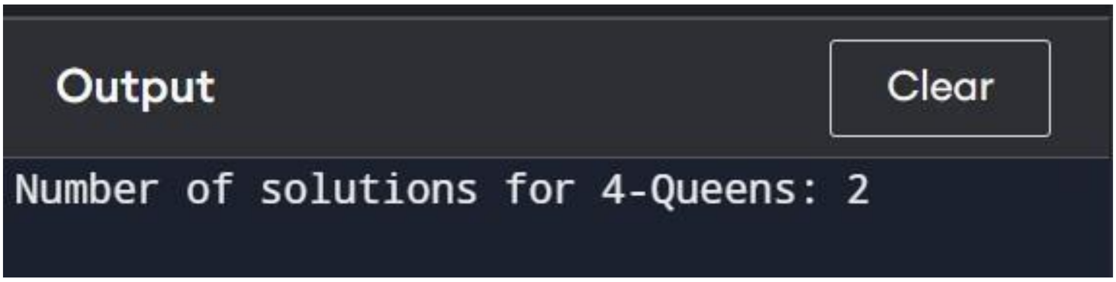
CODE:

```
#include <iostream> #include <vector> using namespace std;  void solve(int
row, int n, vector<int> &cols, vector<int> &diags1, vector<int>
&diags2, int &count) {     if
(row == n) {
++count;         return;
    }      for (int col = 0; col < n; ++col) {          if (cols[col] || diags1[row -
col + n - 1] || diags2[row + col]) continue;
cols[col] = diags1[row - col + n - 1] = diags2[row + col] = 1;         solve(row
+ 1, n, cols, diags1, diags2, count);         cols[col] = diags1[row -
col + n - 1] = diags2[row + col] = 0;
    }  }  int
totalNQueens(int n) {
    vector<int> cols(n, 0), diags1(2 * n - 1, 0), diags2(2 * n - 1, 0);
int count = 0;
    solve(0, n, cols, diags1, diags2, count);
```

```
return count;
}  int

main() {

int n = 4;
   cout << "Number of solutions for " << n << "-Queens: " << totalNQueens(n) <<
endl;     return 0; }
```



Very Hard:

5. Word Ladder II

A transformation sequence from word beginWord to word endWord using a dictionary wordList is a sequence of words beginWord -> s1 -> s2 -> ... -> sk such that:
Every adjacent pair of words differs by a single letter.
Every si for 1 <= i <= k is in wordList. Note that beginWord does not need to be in wordList. sk == endWord
Given two words, beginWord and endWord, and a dictionary wordList, return all the shortest transformation sequences from beginWord to endWord, or an empty list if no such sequence exists. Each sequence should be returned as a list of the words [beginWord, s1, s2, ..., sk].

Example 1:
Input: beginWord = "hit", endWord = "cog", wordList = ["hot","dot","dog","lot","log","cog"]
Output: [["hit","hot","dot","dog","cog"],["hit","hot","lot","log","cog"]]
Explanation: There are 2 shortest transformation sequences:
"hit" -> "hot" -> "dot" -> "dog" -> "cog" "hit" -> "hot" -> "lot" -> "log" -> "cog"

Example 2:
Input: beginWord = "hit", endWord = "cog", wordList = ["hot","dot","dog","lot","log"]

Output: []
Explanation: The endWord "cog" is not in wordList, therefore there is no valid transformation sequence.

Constraints:
1 <= beginWord.length <= 5 endWord.length == beginWord.length 1 <= wordList.length <= 500 wordList[i].length == beginWord.length beginWord, endWord, and wordList[i] consist of lowercase English letters.
beginWord != endWord
All the words in wordList are unique.
The sum of all shortest transformation sequences does not exceed 105.
CODE:

```
#include <iostream>
#include <vector>
#include <unordered_set> #include <queue> using namespace std;
vector<vector<string>> findLadders(string beginWord, string
endWord,
vector<string> &wordList) {
   unordered_set<string> dict(wordList.begin(), wordList.end());
vector<vector<string>> result;
   if (dict.find(endWord) == dict.end()) return result;

   queue<vector<string>> paths;
paths.push({beginWord});      int level =
1, minLevel = INT_MAX;
unordered_set<string> visited;
while (!paths.empty()) {
vector<string> path = paths.front();
      paths.pop();         if (path.size() > level) {              for
(const string &word : visited) dict.erase(word);
visited.clear();             level = path.size();
         if (level > minLevel) break;
      }

      string last = path.back();         for
(int i = 0; i < last.size(); ++i) {
string next = last;
         for (char c = 'a'; c <= 'z'; ++c) {
next[i] = c;
```

```
                if (!dict.count(next)) continue;
visited.insert(next);
vector<string> newPath = path;
newPath.push_back(next);                  if (next
== endWord) {
result.push_back(newPath);

                    minLevel = level;
                } else {
paths.push(newPath);
                }
            }
        }     }
return result;
}  int

main() {

    string beginWord = "hit", endWord = "cog";      vector<string>
wordList = {"hot", "dot", "dog", "lot", "log", "cog"};
vector<vector<string>> result = findLadders(beginWord, endWord, wordList);
for (const auto &path : result) {          for (const string &word : path) {             cout
<< word << " ";
        }
        cout << endl;
    }
return 0;
}
```

Output

```
hit hot dot dog cog
hit hot lot log cog
```
